Brook trout are opportunistic feeders and will eat a variety of insects, fish, and other small animals. Their diet includes mayflies, stoneflies, caddisflies, midges, and other aquatic insects. They will also eat small fish, frogs, and salamanders.

Brook trout spawn in the fall. The female fish will lay her eggs in a redd, which is a depression in the gravel. The male fish will then fertilize the eggs. The eggs will hatch in the spring, and the fry will emerge from the redd. The fry will spend the first few months of their lives feeding on zooplankton and other small organisms. As they grow, they will begin to eat larger prey items, such as insects and fish.

Brook trout are native to eastern North America. They are found in the United States, Canada, and Mexico. In the United States, brook trout are found in the eastern half of the country, from Maine to Georgia. They are also found in the Great Lakes region and in the Rocky Mountains.

Brook trout populations have declined in recent years due to a number of factors, including habitat loss, pollution, and overfishing. Brook trout are listed as a threatened or endangered species in several states. There are a number of conservation efforts underway to protect brook trout populations. These efforts include habitat restoration, stocking, and regulations on fishing.
